Hawaii Soil Health Test Report
University of Hawai'i
College of Tropical Agriculture and Human Resources

Client: Kuliile Farm
Plots: Veggie Plot, Cacao Plot
Soil series: Kaiwika; Hydrous, ferrhydric, isothermic Acrudoxic Hydraludands

Soil health is defined as "the continued capacity of soil to function as a vital living ecosystem that sustains plants, animals and humans" (NIHCS, 2018). Healthy soils ensure that the following critical services are provided: clean air and water, productive crop and grazing lands, thriving forests, diverse wildlife and scenic landscapes. Assessing soil health requires an evaluation of the physical, chemical, and biological state of the soil. CTAHR is currently developing a soil health test that will enable farmers, ranchers, and land managers monitor the effects of land use on soil health. The first step in this process is to select a suite of indicators (measurements) that best describe the physical, chemical, and biological state of a soil. This report presents results of a preliminary set of indicators best suited to characterizing soil health for Hawai'i's diverse soils and landscapes. In Table 1 we present these indicators for soil physical, chemical, and biological properties and describe the significance of each indicator in relation to soil function.

Indicator	Function and Interpretation
Physical Properties	
Bulk density (g/cm ³)	Porosity and rooting environment; lower values are better; low bulk density soils are light, porous, and promote root growth
Water holding capacity (%)	Plant water relations; higher is better
Water stable aggregates (%)	Water infiltration, porosity, aeration; higher is better; soils with a high percentage of stable aggregates promote water infiltration, hold water, have high porosity, and promote root growth
Chemical Properties	
pH	Nutrient availability; 6.0-7.0 is ideal, this is the pH range where plant essential elements are most available and toxicities are negligible
Total organic carbon (%)	Natural resource reserve and overall soil function; higher is better; TOC is a measure of the amount of soil organic matter in soil, soil organic matter benefits all aspects of soil function
Hot water extractable organic C (mg kg ⁻¹)	Energy source for microbes and readily mineralizable N; higher is better; this pool of extractable C is involved in aggregate formation in addition to its bioavailability
Biological Properties	
CO ₂ burst (mg C kg ⁻¹)	Metabolic activity of microbes; high equals active microbial community
Mineralizable nitrogen (mg kg ⁻¹)	Soil biological activity and available substrate for N mineralization; higher is better; this is a measure of the soil's natural capability to supply plant available N
β-glucosidase (mg kg ⁻¹)	Microbially produced enzyme associated with C decomposition; higher is better; a measure of soil's natural ability to cycle C
β-glucosaminidase (mg kg ⁻¹)	Microbially produced enzyme associated with N mineralization; higher is better, a measure of soil's natural ability to cycle N

Soil Fertility

Managing soil nutrient status in soils to create optimum conditions for plant growth in relation to agricultural sustainability and environmental protection. (B.R. Singh, 2002)

Soil fertility depends on:

- Inherent soil properties (physical and chemical properties, clay mineralogy)
- Soil organic matter
- Climate (soil moisture & temperature)

Soil Fertility Test

1. *Diagnosis*

Rapid chemical analyses to assess the plant-available nutrient status, salinity, and elemental toxicity of a soil in relation to crops.

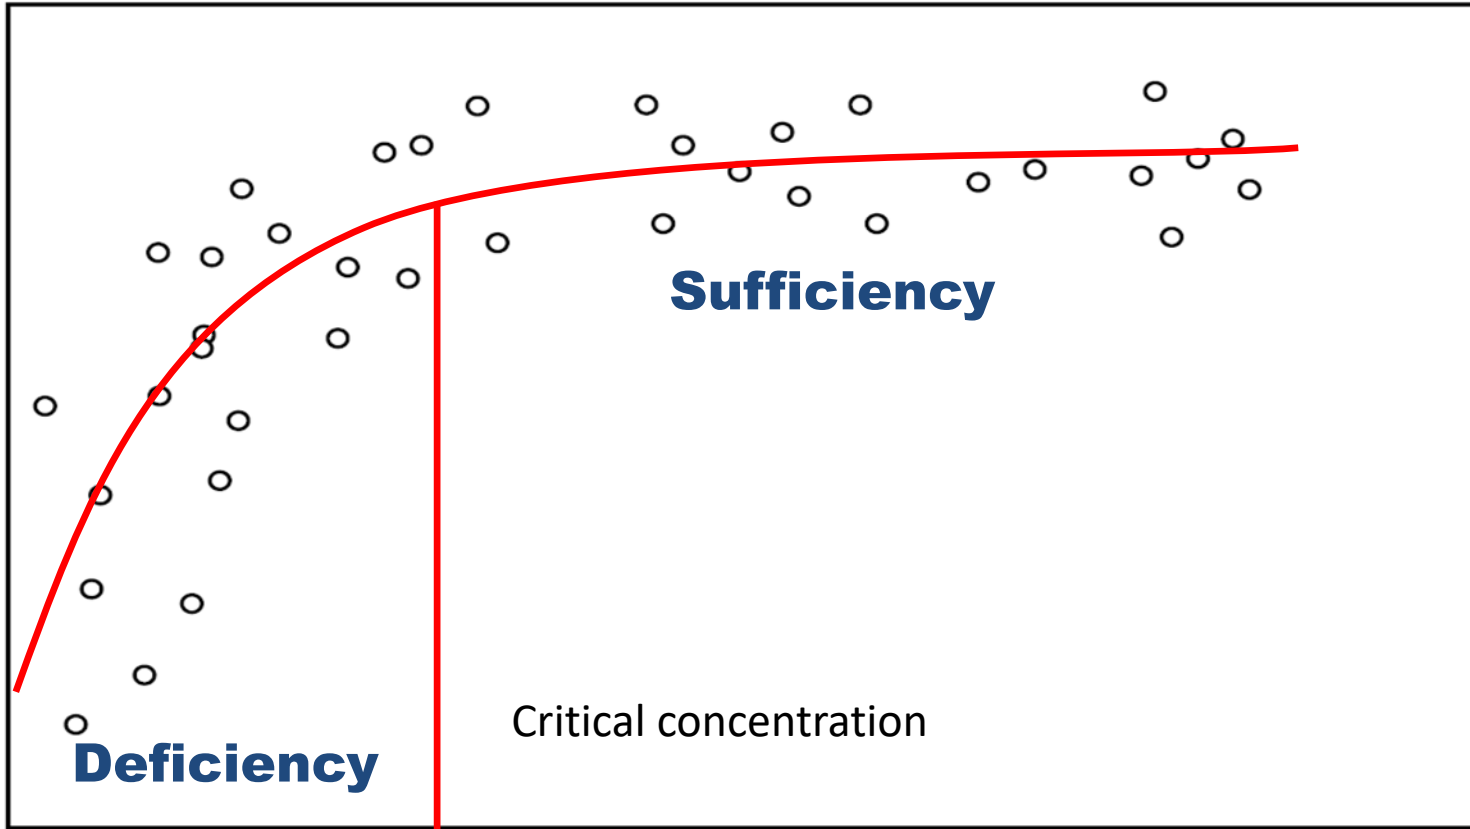

2. *Interpretation*

- Deficiency – sufficiency – excessive
- Non-toxic - toxic

3. *Recommendation*

- What to add?
- How much to add?
- When to add?
- Where to place?

Plant Response (Relative Yield)

Soil Test Level

i.e., extractable Ca or P (ppm)

Soil Health

- Soil health is a metaphor with the following elements:
 - Functionality: promotes utility and processes that maintain integrity and stability of biosphere
 - Vitality: soil is a living system, a complex assemblage of numberless and mostly nameless biota mediating basic soil processes and plant interactions
 - Sustainability/Resilience: a soil's enduring capacity to promote its myriad functions in the face of disturbance

Hawaii Soil Health Test

Hawaii Soil Health Test Report

University of Hawai'i

College of Tropical Agriculture and Human Resources

- Does crop performance respond to a soil health score?

This is a critical area of inquiry that is needed to help guide how we best use the results of a soil health test.

Interpretation

Soil Fertility

- Soil has very low nutrient status – especially P, Ca, and K

Soil Health

- Soil is rich in organic matter
- Soil health tied to soil organic matter

Recommendation

Soil Fertility

- Manure applications to build soil P and Ca
- Sulfate of potash to raise soil K

Soil Health

- Manure will likely improve soil health score

Kuilike Farm

Take Home

- Soil fertility and soil health testing are different and both useful
- A soil fertility test provides a diagnosis from which a clear and actionable recommendation can be made
- A soil health test is more nuanced and the results are highly influenced by soil organic matter status
- Soil health testing is useful to monitor trends over time related to soil management strategies
- Soil health is not directly correlated with crop yields
